1. Show that if a continuous, differentiable function $f(x): \mathbb{R} \rightarrow \mathbb{R}$ has a local minimum at a point x_0 , then $f'(x_0) = 0$.

Consider the function $f(x)$

The gradient of the curve at x_0 = gradient of tangent at x_0 .

$$f'(x_0) = \frac{f(x_0+h) - f(x_0)}{(x_0+h) - x_0} = \frac{f(x_0+h) - f(x_0)}{h}$$

$\lim_{h \rightarrow 0^+} f'(x_0) \geq 0$ and $\lim_{h \rightarrow 0^-} f'(x_0) \leq 0$, then

at the local ^{minimum} point $f'(x_0) = 0$

2. Counter example.

Consider a function $f(x) = 3x + 2x^2$
 $\forall x \in [0, 1]$

$$\text{at } x=0 \Rightarrow f(0) = 0$$

$$f'(0) = 3 + 4x \Rightarrow f'(0) = 3 \neq 0, \text{ hence it is not sufficient.}$$

2. Show that, if a differential function $J(x) = f(x) + \lambda g(x)$ has a local minimum at a point x_0 , then $g(x_0) = 0$.

$$J(x) = f(x) + \lambda g(x) \quad \text{--- (1)}$$

differentiating (1) w.r.t λ

$$\frac{\partial J(x)}{\partial \lambda} = g(x)$$

$$\left. \frac{\partial J(x)}{\partial \lambda} \right|_{x=x_0} = g(x_0) = 0.$$

□

3. Duhamel's principle

$$u_t + cu_x = f(x, t)$$

The resulting solution is

$$u(x, t) = u(x - ct, 0) + \int_0^t f(x - c(t - \tau), \tau) d\tau$$

Use this solution to obtain the fundamental

(2)

Solution $G_0(x, t, \xi, \tau)$ for the equation

$$\text{Since } u_t + cu_x = \delta(t-\tau) \delta(x-\xi), \\ (x, t) \in (-\infty, \infty) \times [0, T]$$

$$u(x, t) = u(x - ct, 0) + \int_0^t f(t - c(t-\tau), \tau) d\tau$$

Can be written as,

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \int_0^t f(x - c(t-\tau), \tau) d\tau \quad \dots \text{--- (1)}$$

$$\text{Since } u_t + cu_x = f(x, t) = \delta(t-\tau) \delta(x-\xi) \\ f(x, t) = \delta(t-\tau, x-\xi)$$

So

$$f(x - c(t-\tau), \tau) = \delta(x - c(t-\tau) - \xi) \delta(\tau - \tau) \\ = \delta(x - c(t-\tau) - \xi, 0)$$

then equation (1) becomes

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \int_0^{t-\tau} \delta(x - \xi - c(t-\tau-\eta), \eta) d\eta$$

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \int_0^{t-\tau} \delta(x - \xi - c(t-\tau) + c\eta) \delta(\eta) d\eta$$

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \int_0^{t-\tau} \delta\left(c\left(\frac{1}{c}(x - \xi) - (t-\tau) + \eta\right)\right) \delta(\eta) d\eta$$

$$\text{Using a property } \delta(c\eta) = \frac{1}{|c|} \delta(\eta)$$

$$\frac{1}{c} G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \frac{1}{c} \int_0^{t-\tau} \delta\left(\eta + \frac{1}{c}(x - \xi) - (t-\tau)\right) \delta(\eta) d\eta$$

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \frac{1}{c} \int_0^{t-\tau} \delta(\eta - (t-\tau) - \frac{1}{c}(x-\xi)) \delta(\eta) d\eta$$

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \frac{1}{c} \delta((t-\tau) - \frac{1}{c}(x-\xi)) H(t-\tau)$$

$$\text{Since } \int_{-\infty}^{\infty} \delta(\eta - a) \delta(\eta - b) d\eta = \delta(a - b)$$

So

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \delta(c(t-\tau) - (x-\xi)) H(t-\tau)$$

Since $\delta(x)$ is an even function i.e. $\delta(-x) = \delta(x)$
then

$$G(x, t, \xi, \tau) = G(x - ct, 0, \xi, \tau) + \delta(x - \xi - c(t-\tau)) H(t-\tau)$$

$$\text{where } H(t-\tau) = \begin{cases} 0, & t < \tau \\ 1, & t > \tau \end{cases}$$

4) (Euler Lagrange equations) Consider the model problem.

$$u_t + c|u_x| \geq 0, \quad c > 0$$

$$u(x, 0) = 0$$

$$u(0, t) = 0$$

a) Show that $f_m = (\hat{u}(x_m, t_m) - d_m)$

$$\hat{u}(x, t) = \sum_{m=1}^M f_m r_m(x, t) \quad \text{--- (1)}$$

differentiate (1) w.r.t t

$$\frac{\partial}{\partial t} \hat{u}(x,t) = \sum_{m=1}^M \beta_m \frac{\partial}{\partial t} f_m(x,t) \quad \text{--- (2)}$$

differentiate (2) w.r.t x

$$\frac{\partial}{\partial x} \hat{u}(x,t) = \sum_{m=1}^M \beta_m \frac{\partial}{\partial x} f_m(x,t) \quad \text{--- (3)}$$

Equation (2) + c (Equation (3))

$$\hat{u}_t(x,t) + c \hat{u}_x(x,t) = \sum_{m=1}^M \beta_m \left(\frac{\partial f_m(x,t)}{\partial t} + c \frac{\partial f_m(x,t)}{\partial x} \right)$$

$$\frac{\partial f_m(x,t)}{\partial t} + c \frac{\partial f_m(x,t)}{\partial x} = \alpha_m$$

$$\hat{u}_t(x,t) + c \hat{u}_x(x,t) = \sum_{m=1}^M \beta_m \alpha_m$$

$$\text{but } \hat{u}_t + c \hat{u}_x = \lambda(x,t)$$

$$\lambda(x,t) = \sum_{m=1}^M \beta_m \alpha_m \quad \text{--- (4)}$$

$$\frac{\partial \lambda}{\partial x} = \sum_{m=1}^M \beta_m \frac{\partial \alpha_m}{\partial x} \quad \text{--- (5)}$$

differentiate (4) w.r.t t

$$\frac{\partial \lambda}{\partial t} = \sum_{m=1}^M \beta_m \frac{\partial \alpha_m}{\partial t} \quad \text{--- (6)}$$

c (Equation (4)) + Equation (6)

$$c \frac{\partial \lambda}{\partial x} + \frac{\partial \lambda}{\partial t} = \sum_{m=1}^M \beta_m \left(\frac{\partial \alpha_m}{\partial t} + c \frac{\partial \alpha_m}{\partial x} \right)$$

but

$$\frac{\partial x_m}{\partial t} + c \frac{\partial x_m}{\partial x} = -\delta(x - x_m) \delta(t - t_m)$$

and

$$c \lambda_x + \lambda_t = \sum_{m=1}^M (\hat{u}(x, t) - d_m) \delta(x - x_m) \delta(t - t_m)$$

$$\sum_{m=1}^M (\hat{u}(x, t) - d_m) \delta(x - x_m) \delta(t - t_m) = \sum_{m=1}^M f_m (-\delta(x - x_m) \delta(t - t_m))$$

$$\hat{u}(x_m, t_m) - d_m = -f_m$$

c) Using (4), show that solutions for $x_m(x, t)$ and $r_m(x, t)$ are given by

$$x_m(x, t) = \delta(x - x_m - c(t - t_m)) H(t_m - t), \quad m = 1, 2, 3, \dots, M$$

$$G(x, \eta, t, \tau) = G(x - ct, 0, \eta, \tau) + \delta(x - \eta - c(t - \tau)) H(t - \tau)$$

but $G(x - ct, 0, \eta, \tau) = 0$ at the boundary.
replace η with x_m , and τ with t_m

$$G(x, x_m, t, t_m) = \delta(x - x_m - c(t - t_m)) H(t - t_m) = x_m(x, t)$$

so

$$-x_m(x, t) = \delta(x - x_m - c(t - t_m)) H(t - t_m)$$

dividing through by negative.

(4)

$$\alpha_m(x, t) = \delta(x - x_m - c(t - t_m)) H(t_m - t)$$

$$r_m(x, t) = \delta(x - x_m - c(t - t_m)) (t + (t_m - t) H(t - t_m))$$

$m = 1, 2, \dots, M$

$$\frac{\partial r_m}{\partial t} + c \frac{\partial r_m}{\partial x} = \alpha_m$$

$$r_m(x, t) = \int_0^t \alpha_m(x_0 - c(t - \eta), \eta) d\eta$$

$$r_m(x, t) = \int_0^t \delta(x - c(t - \eta) - x_m - c(\eta - t_m)) H(t_m - \eta) d\eta$$

$$= \int_0^t \delta(x - ct + c\eta - x_m - c\eta + ct_m) H(t_m - \eta) d\eta$$

$$r_m(x, t) = \int_0^t \delta(x - x_m - c(t - t_m)) H(t_m - \eta) d\eta$$

$$r_m(x, t) = \delta(x - x_m - c(t - t_m)) \int_{t_m - t}^t H(t_m - \eta) d\eta$$

$$r_m(x, t) = \delta(x - x_m - c(t - t_m)) (-R(t_m - \eta)) \Big|_{t_m - t}^t$$

$$r_m(x, t) = \delta(x - x_m - c(t - t_m)) (-R(t_m - t) + R(t_m - (t_m - t)))$$

$$r_m(x, t) = \delta(x - x_m - c(t - t_m)) (R(t) - R(t_m - t))$$

$$\text{but } R(x) = x H(x)$$

$$r_m(x, t) = \delta(x - x_m - c(t - t_m)) (t H(t) - (t_m - t) H(t_m - t))$$

$$f_m(x, t) = \delta(x - x_m - c(t - t_m)) \cdot (t + (t_m - t)) H(t - t_m)$$

$m = 1, 2, \dots, M$

4(b) Using (b) formulate a linear system

$$(R + I) \beta = d$$

using $\hat{u}(x_m, t_m) - d_m = -\beta_m$ — (1) from 4(a) and then

$$\hat{u}(x, t) = \sum_{m=1}^M \beta_m r_m(x, t) \quad \text{--- (2)}$$

Since $r_j = r_j(x_j, t_j)$ then (2) can be written as

$$\hat{u}(x_j, t_j) = \sum_{m=1}^M \beta_m r_m(x_j, t_j), \quad j = 1, 2, \dots, M$$

from Equation (1), if $\hat{u}(x_m, t_m) = d_m - \beta_m$ then

$$\hat{u}(x_j, t_j) = \sum_{m=1}^M \beta_m r_m(x_j, t_j) = d_j - \beta_j, \quad j = 1, 2, \dots, M$$

$$\sum_{m=1}^M \beta_m r_m(x_j, t_j) + \beta_j = d_j, \quad j = 1, 2, \dots, M$$

$$\beta_1 r_{1j} + \beta_2 r_{2j} + \dots + \beta_M r_{Mj} + \beta_j = d_j, \quad j = 1, 2, \dots, M$$

Since R is symmetric then $r_{ij} = r_i(x_j, t_j) = r_j(x_i, t_i)$

$$\underbrace{\begin{bmatrix} r_{11} & r_{12} & \dots & r_{1M} \\ r_{21} & r_{22} & \dots & r_{2M} \\ \vdots & \vdots & \ddots & \vdots \\ r_{M1} & \dots & \dots & r_{MM} \end{bmatrix}}_R \underbrace{\begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_M \end{bmatrix}}_{\beta} + \underbrace{\begin{bmatrix} 1 & & & \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{bmatrix}}_I \underbrace{\begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_M \end{bmatrix}}_{\beta} = \underbrace{\begin{bmatrix} d_1 \\ d_2 \\ \vdots \\ d_M \end{bmatrix}}_d$$

$$(R\beta + I\beta) = d$$

$$\underline{\underline{(R+I)\beta = d}}$$
