Distributed Memory and Message Passing Interface

PARALLEL PROGRAMMING MODELS

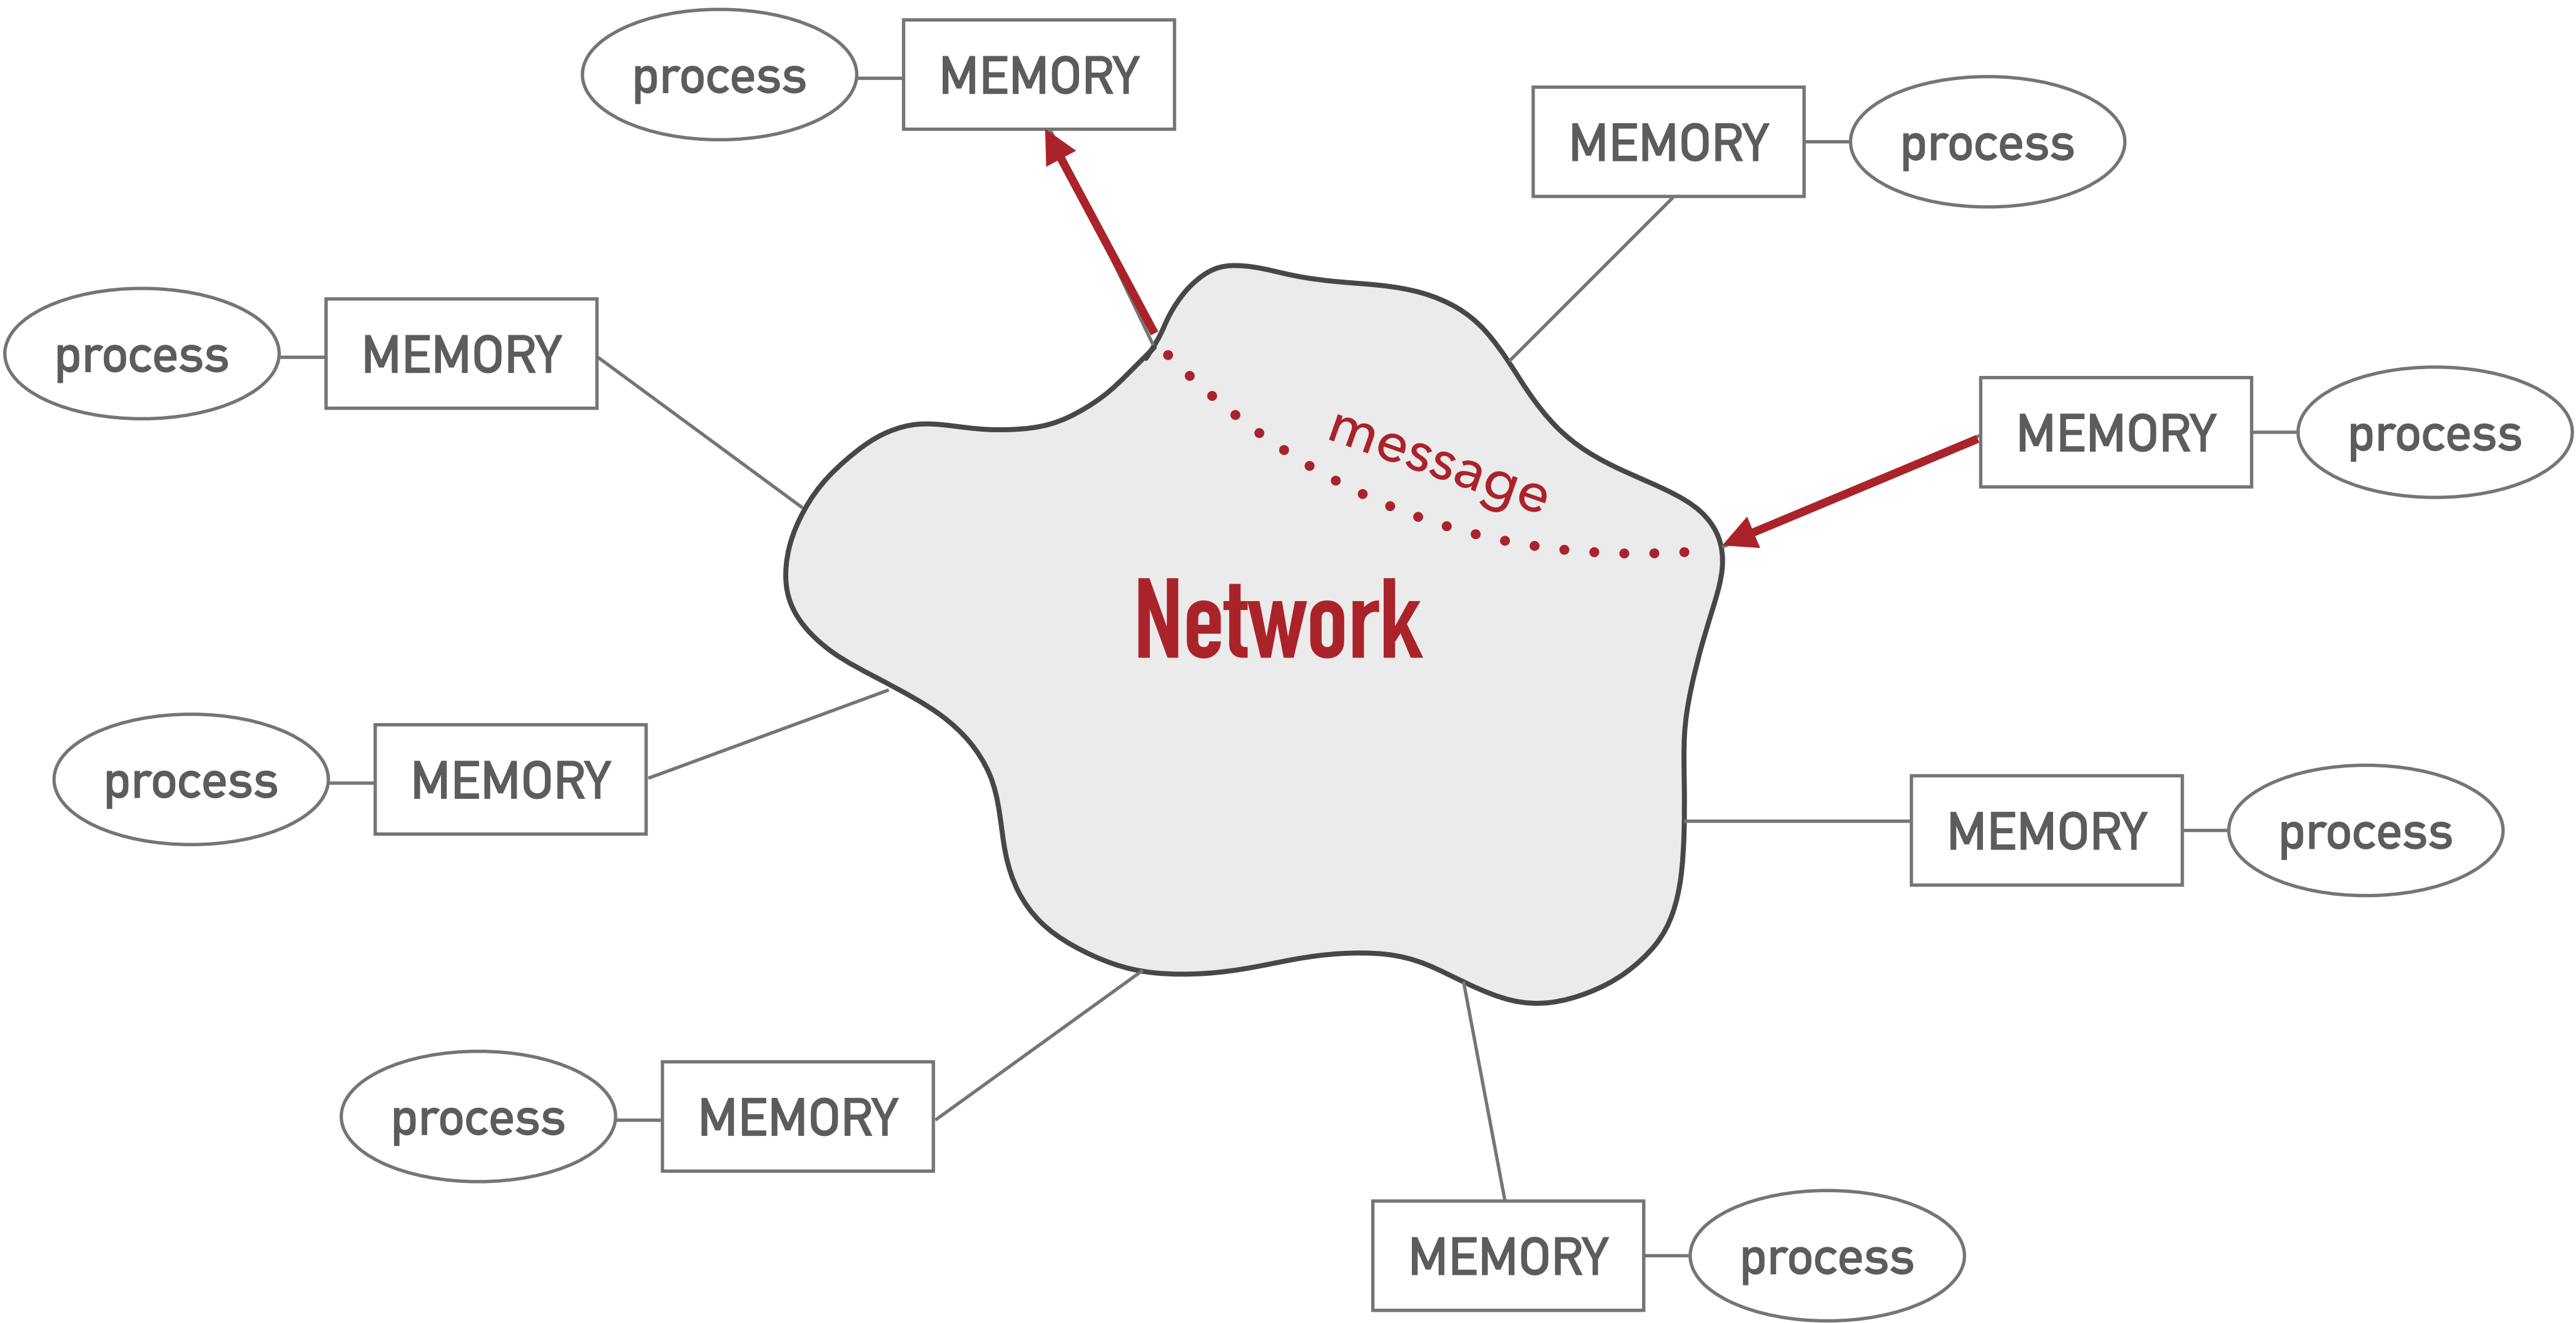

SHARED MEMORY

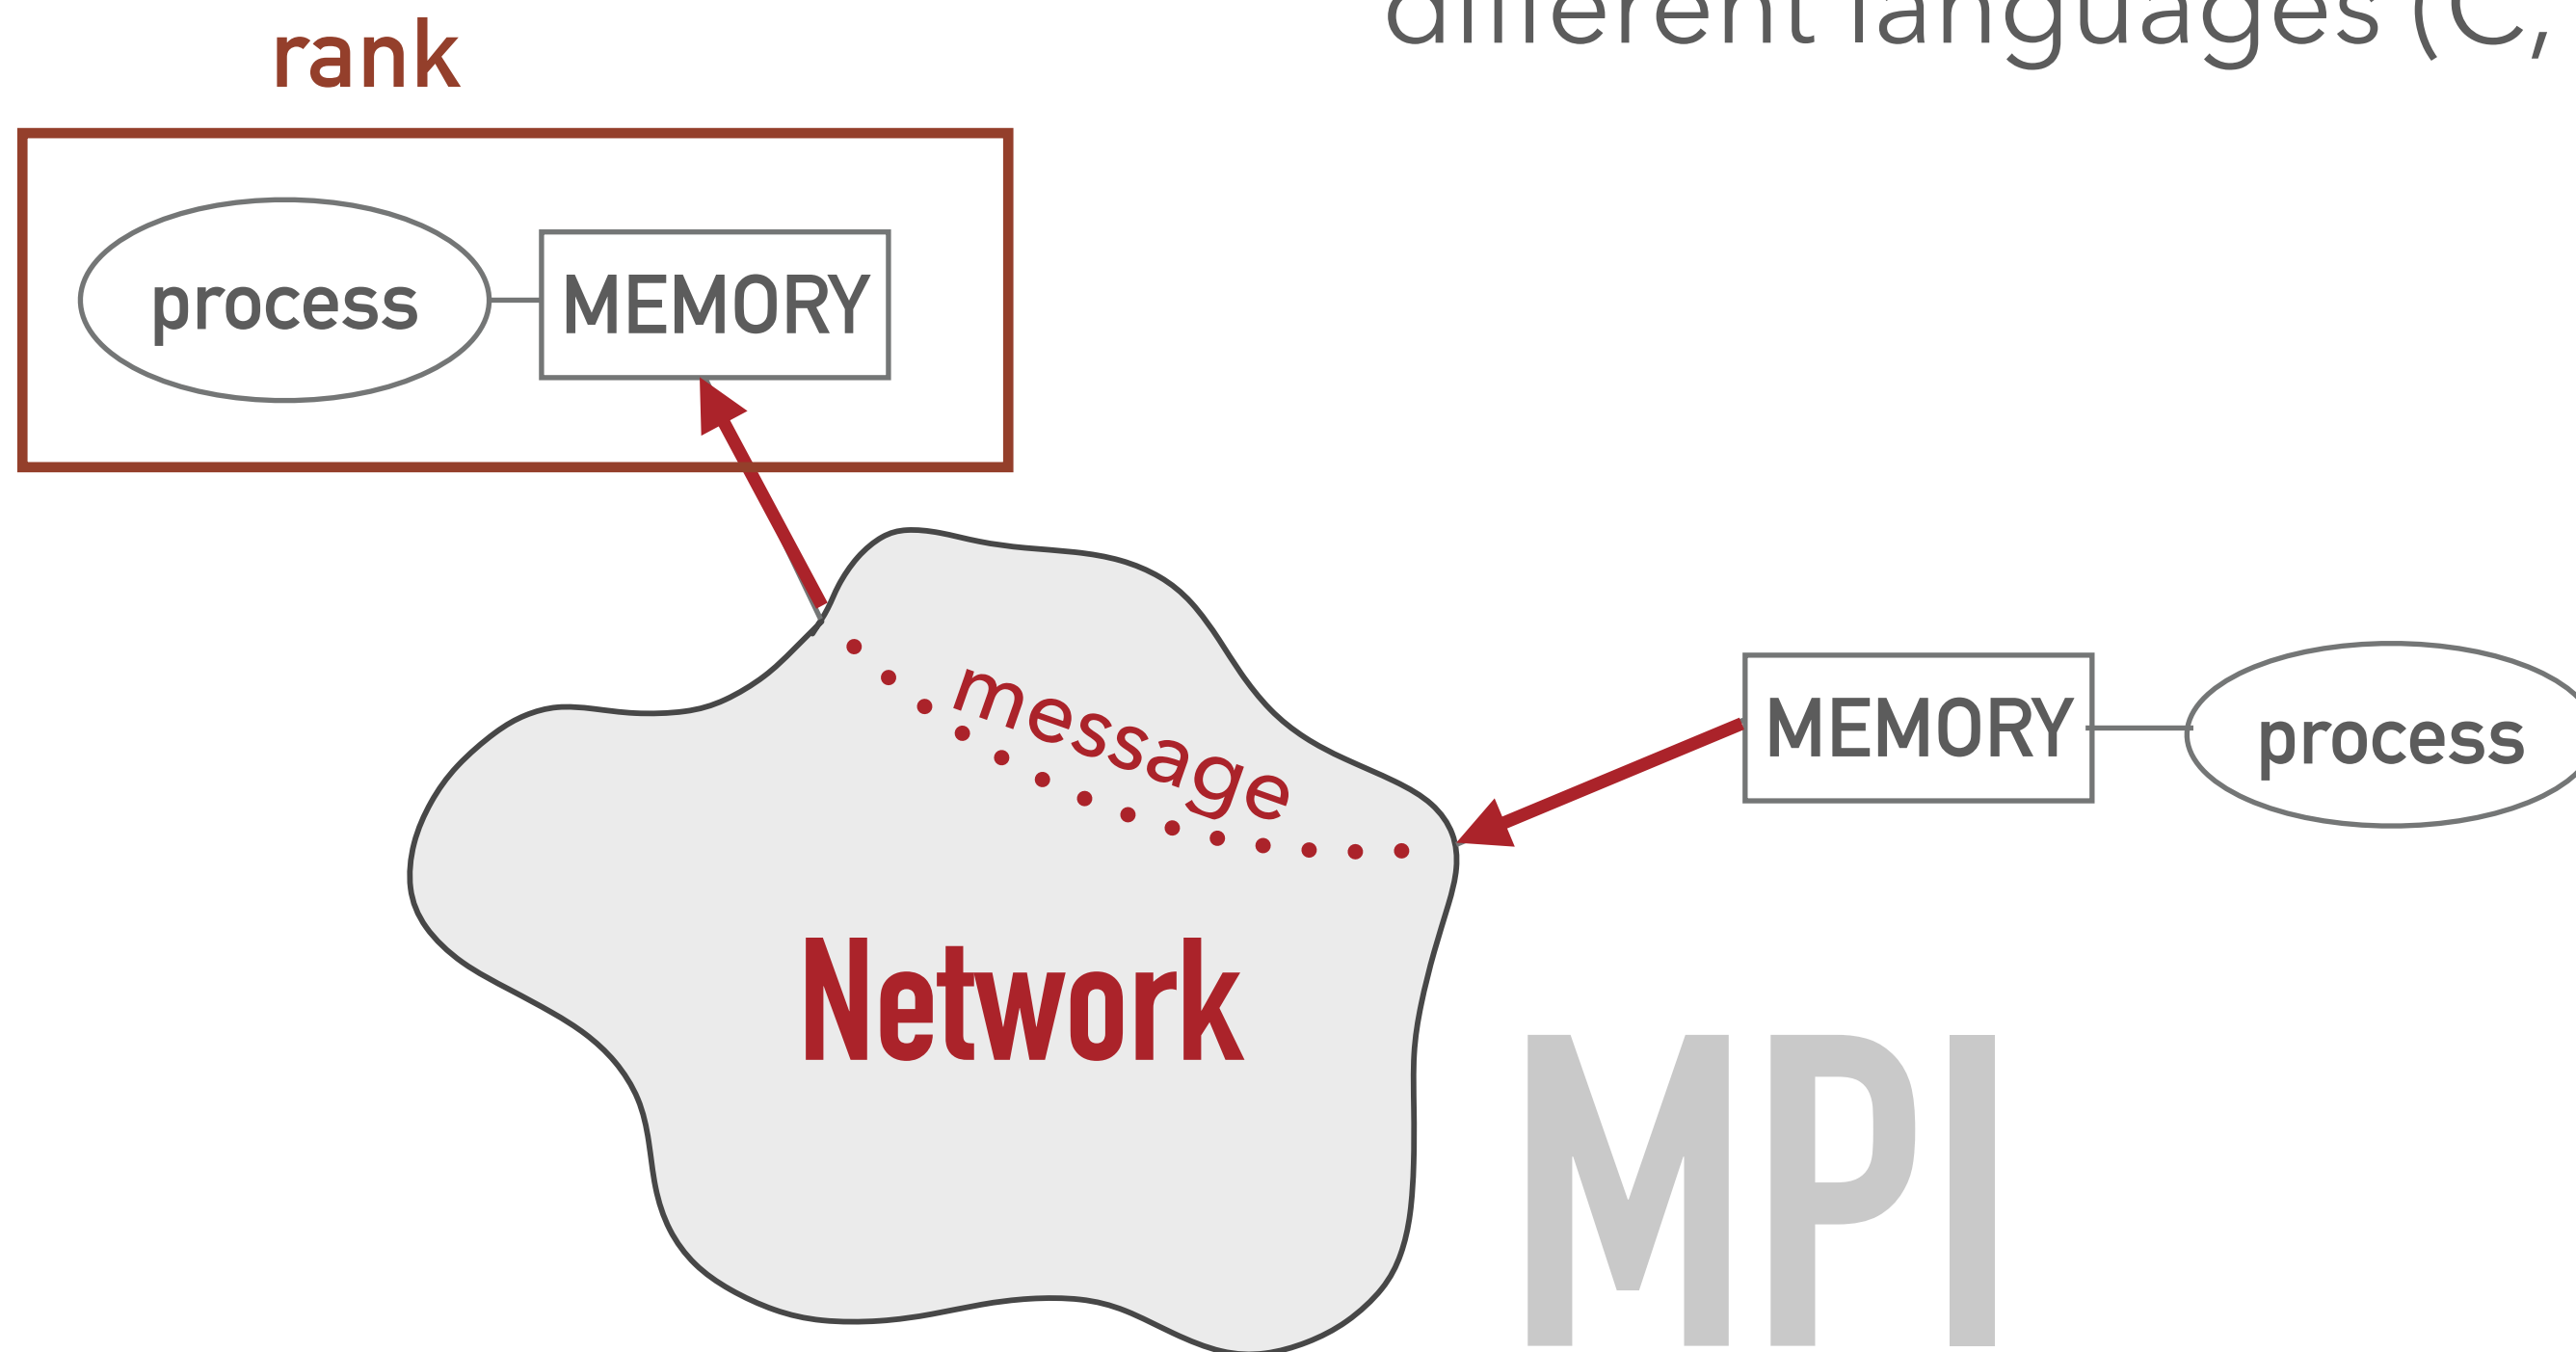

DISTRIBUTED MEMORY

MESSAGE PASSING MODEL

MESSAGE PASSING INTERFACE

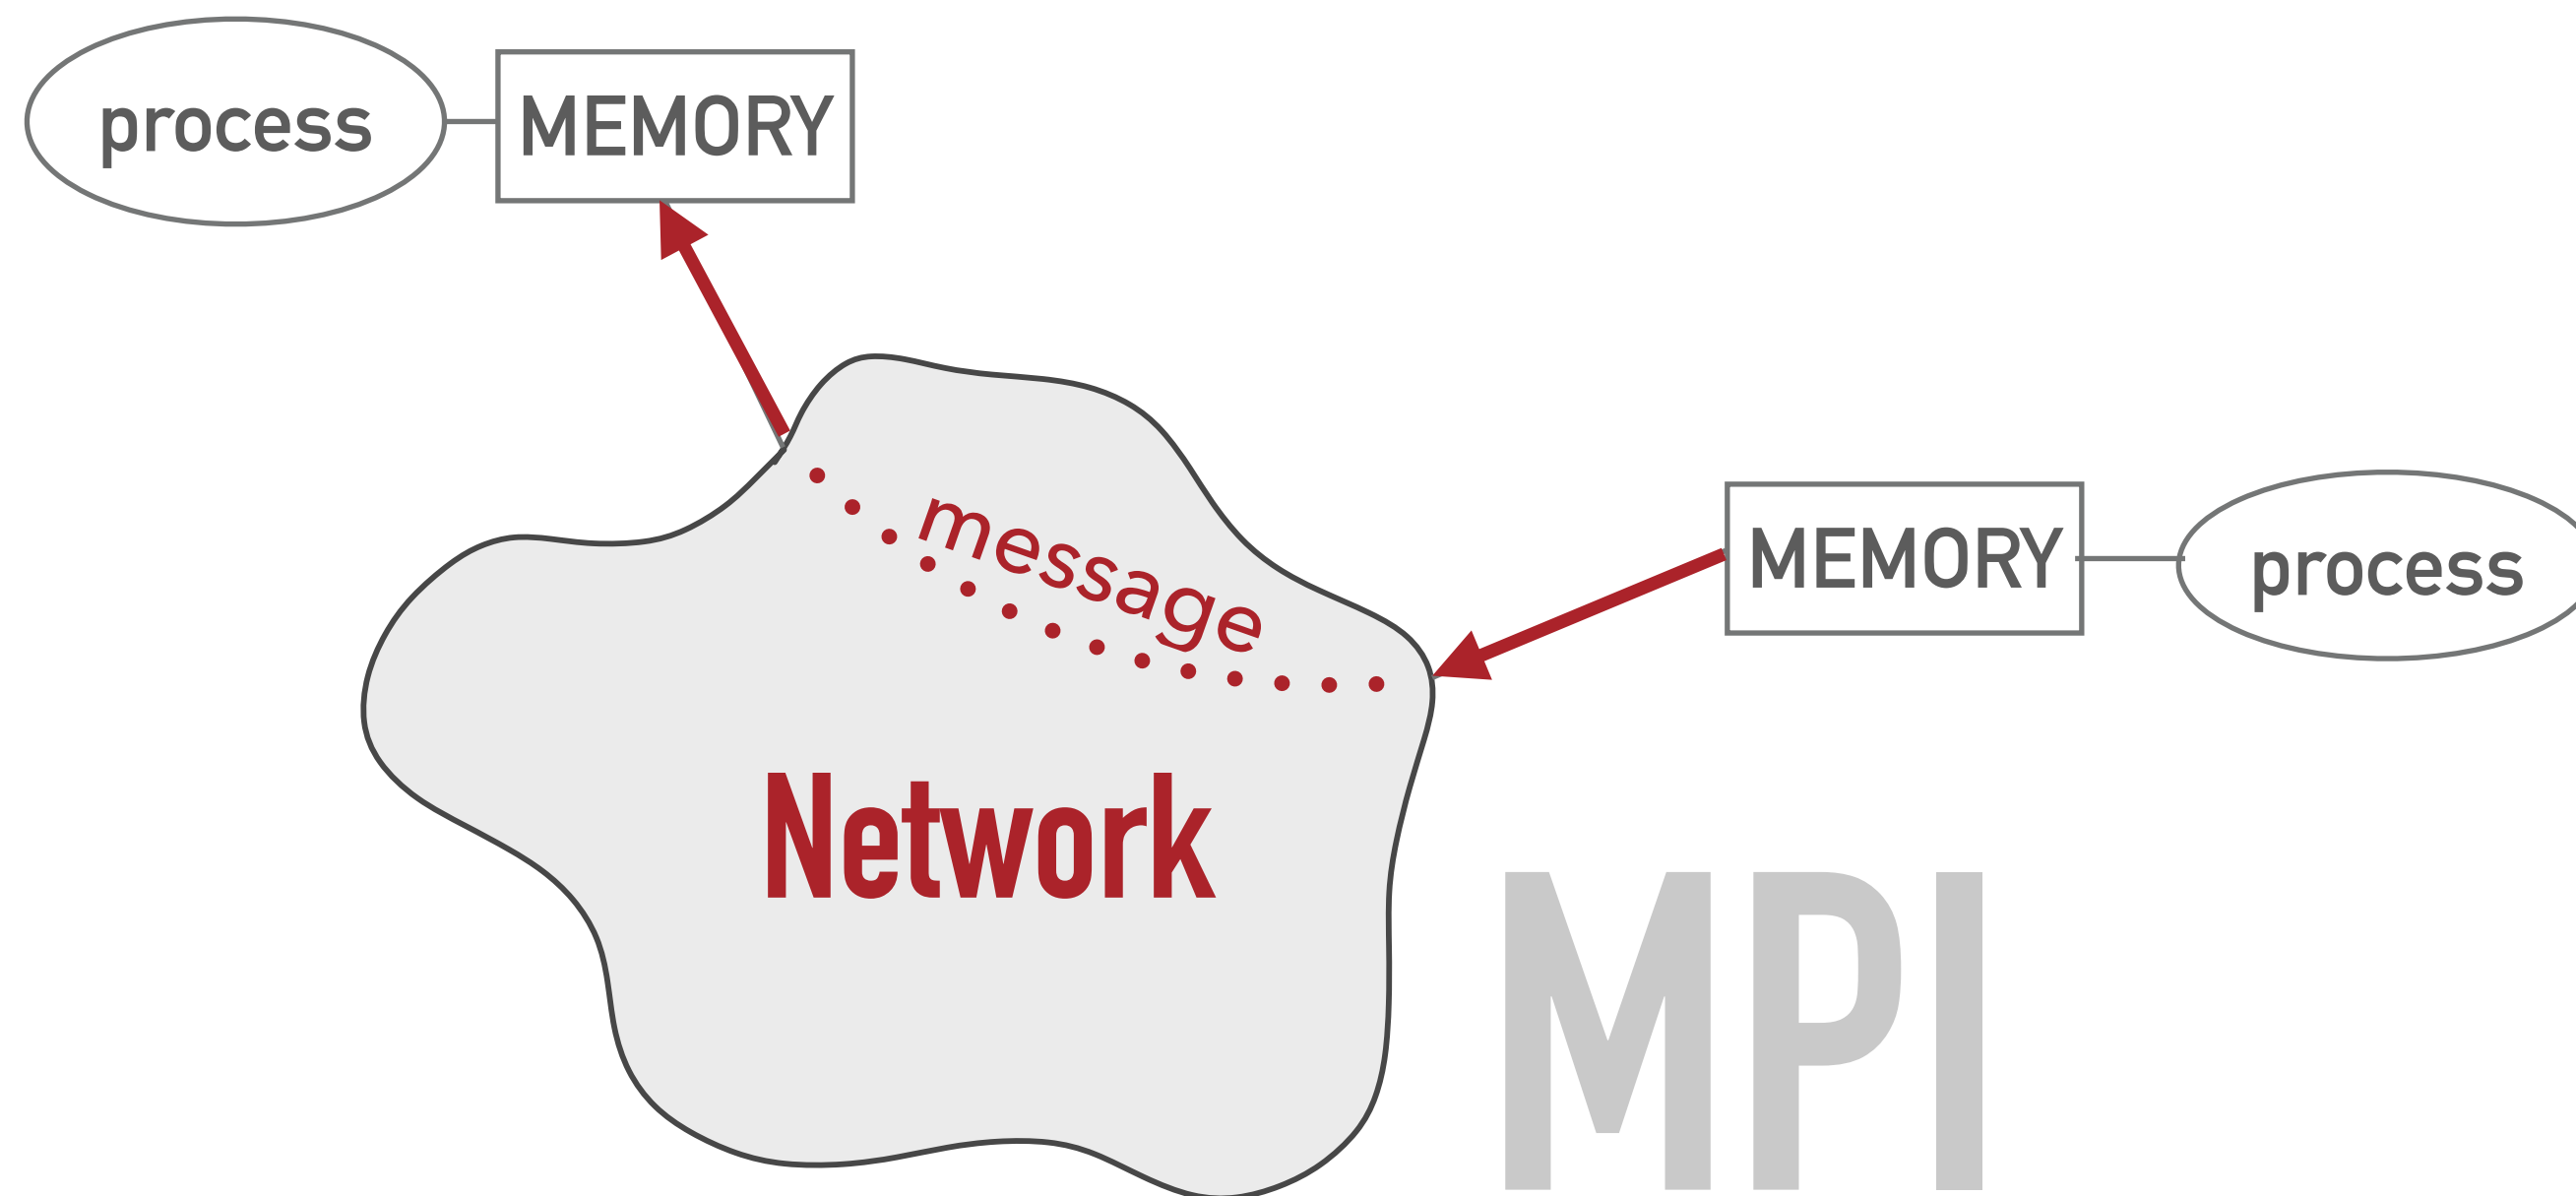

- MPI is a **library** which specifies names and results of subroutines (functions) that allow **passing data** between **processes (ranks)** using **messages**.
- MPI **is not** a programming language. It can be implemented in different languages (C, Fortran, Python)

- There are different implementations of MPI (MPICH, OpenMPI), which can perform better or worse on certain systems

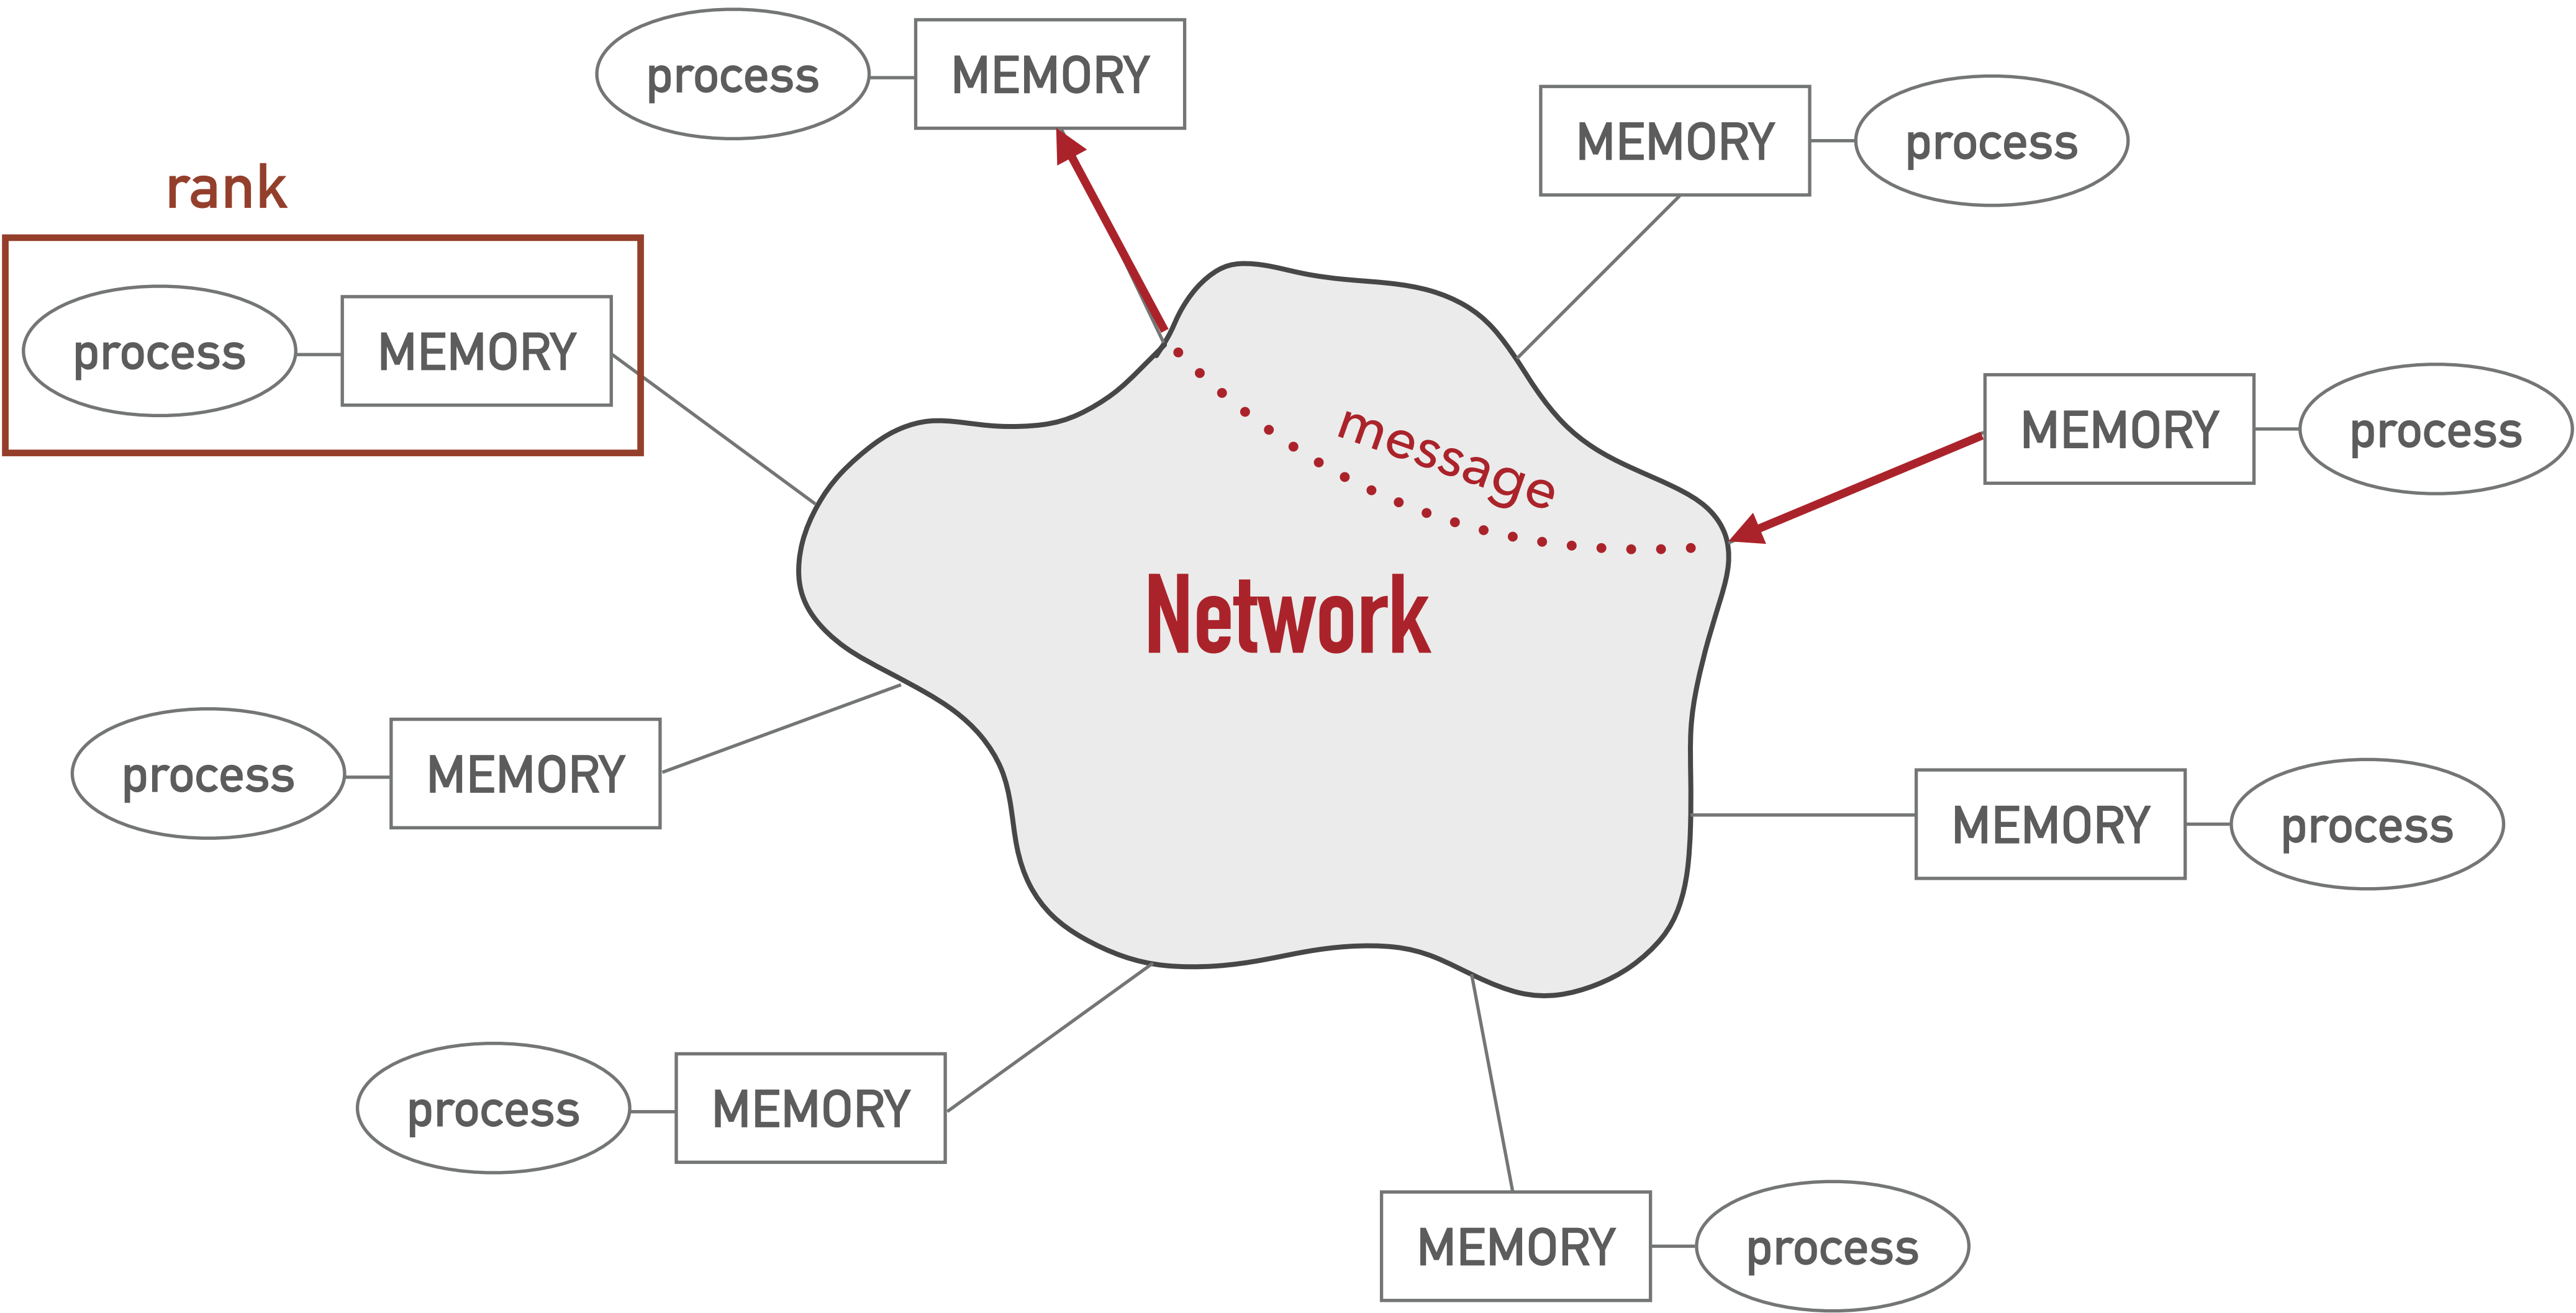

MESSAGE PASSING INTERFACE

- MPI is **universal** - can run on (almost) any system, from supercomputers to clusters of PCs, multicore CPUs, as well as shared memory machines
 - MPI is **expressive** - can implement any algorithm invented by a programmer within the message passing model

- MPI is (relatively) **easy to debug** due to well defined memory ownership

MESSAGE PASSING MODEL

MESSAGE PASSING MODEL

Communicator

- each process has a unique **rank** (number) within communicator
- communicator **size** is the number of ranks (processes) it contains
- ranks can exchange messages within a communicator

MPI_COMM_WORLD - default communicator containing all available ranks

Hello, World!

Hello, World!

H

FUNCTIONAL PARALLELISM

*Different processes perform **different** tasks.*

rank 0 *runs ocean model*

rank 1 *runs atmosphere model*

rank 2 *runs ice model*

rank 3 *runs land model*

DATA PARALLELISM

*Different processes perform **the same** tasks on different data.*

rank 0 *computes derivative on first 1/4 of data*

rank 1 *computes derivative on second 1/4 of data*

rank 2 *computes derivative on third 1/4 of data*

rank 3 *computes derivative on fourth 1/4 of data*

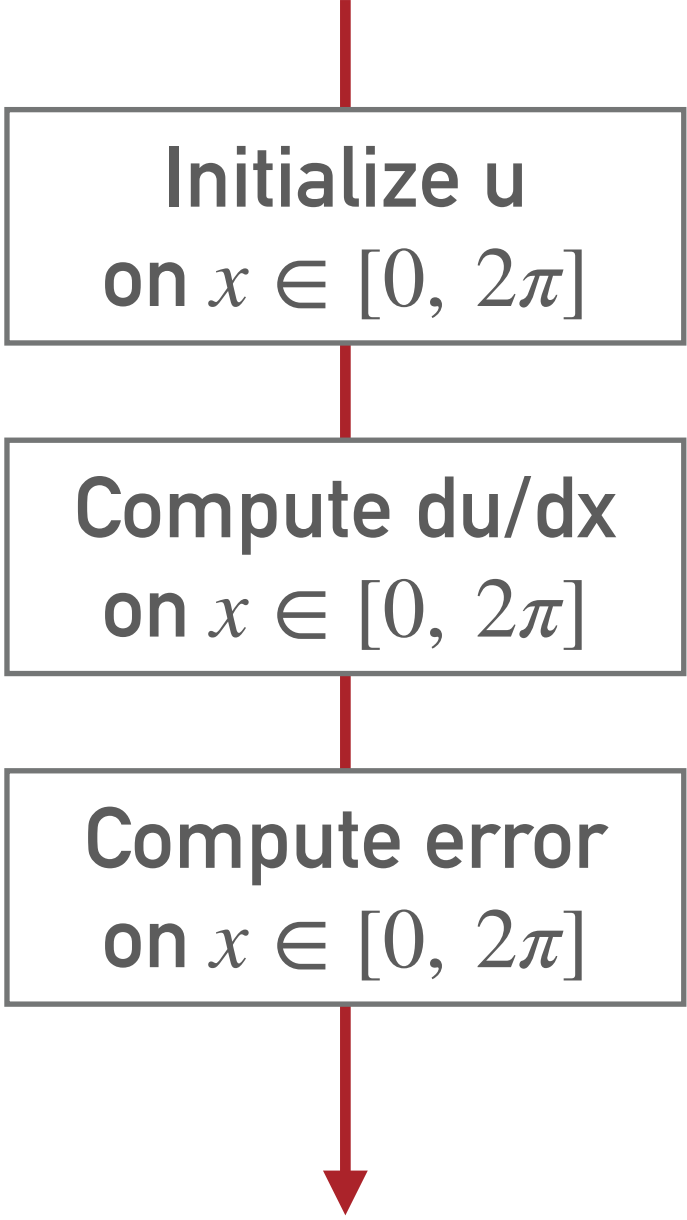

Example of data parallelism - compute the derivative of $\sin(x)$

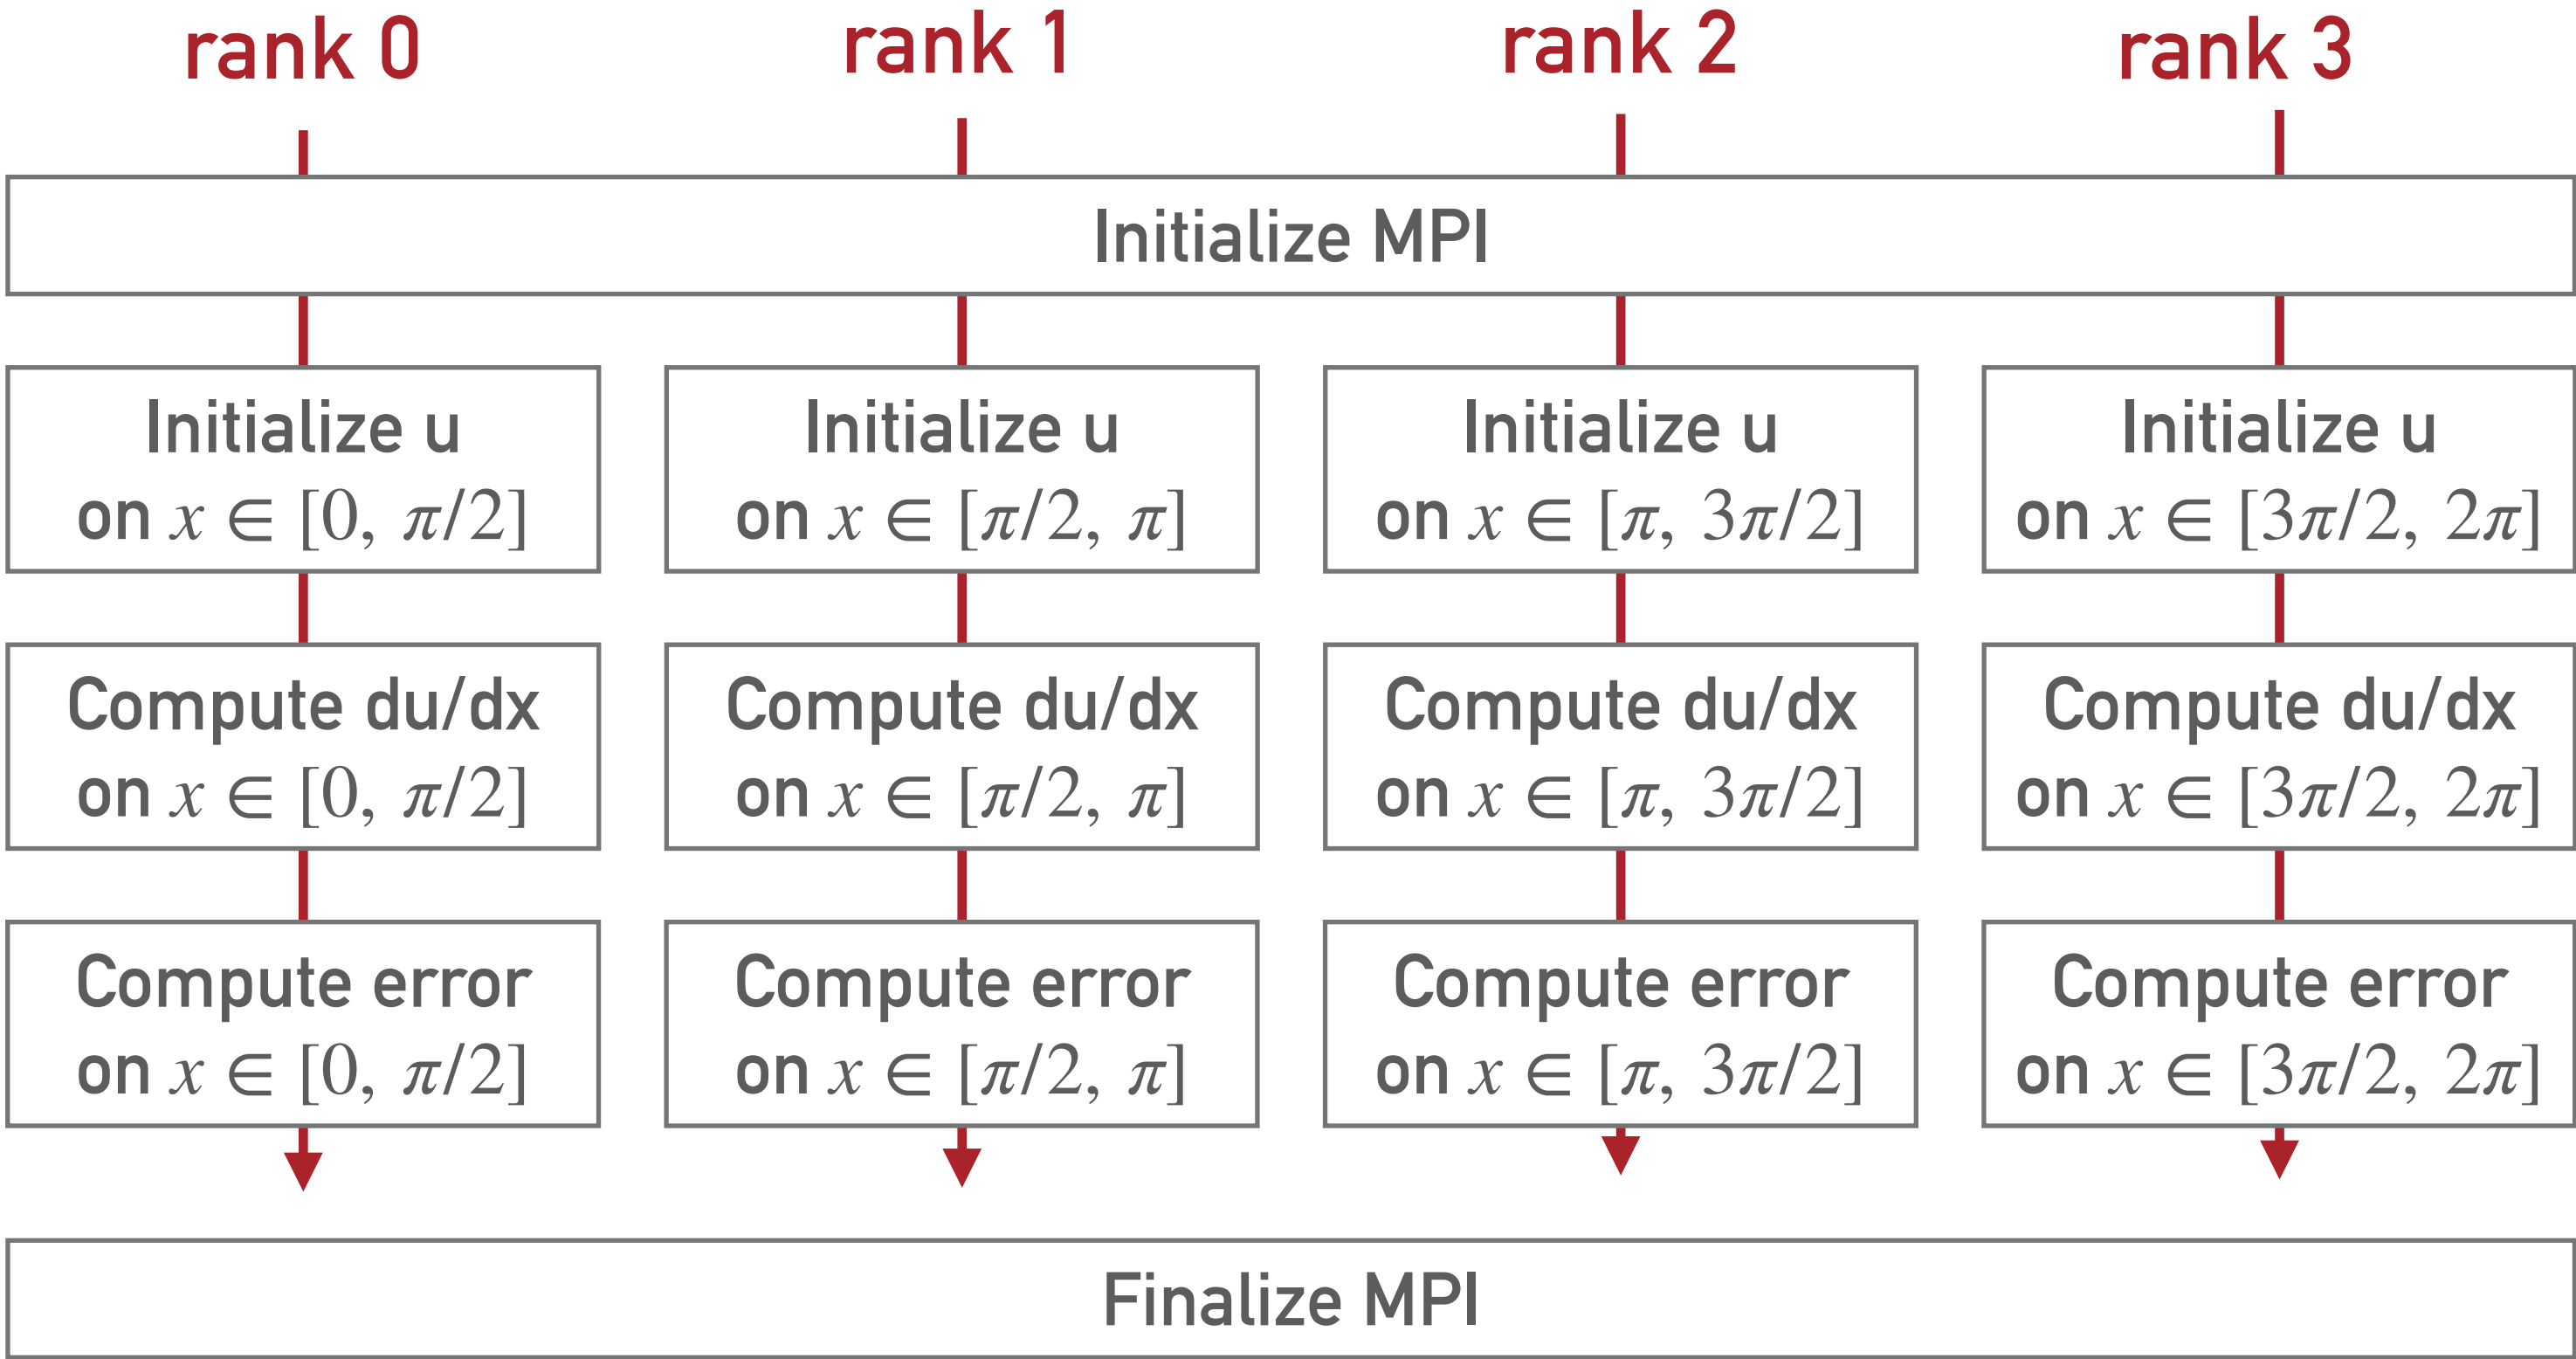

Divide and Conquer: We can divide the work among available ranks, where each rank performs a fraction of the work

DERIVATIVE EXAMPLE

serial program

parallel program

u []

0	1	2	3	4	5	N-2	N-1
---	---	---	---	---	---	-----	--	--	--	--	--	--	--	--	--	--	-----	-----	-----

rank 0

rank 1

rank 2

rank 3

`u[]`

`N = 20`

we have $N = 20$ points in this example

`nproc = 4`

let's say we have 4 ranks in our communicator

`N_loc = N/nproc`

that gives 5 points per rank

rank 0

rank 1

rank 2

rank 3

u []

0	1	2	3	4
---	---	---	---	---

5	6	7	8	9
---	---	---	---	---

10	11	12	13	14
----	----	----	----	----

15	16	17	18	19
----	----	----	----	----

*In the serial code points are numbered with a **global index** $i = 0, \dots, N-1$*

0	1	2	3	4
---	---	---	---	---

0	1	2	3	4
---	---	---	---	---

0	1	2	3	4
---	---	---	---	---

0	1	2	3	4
---	---	---	---	---

0 1 2 3 4

5 6 7 8 9

10 11 12 13 14

15 16 17... 18 19

Each rank processes only a subset of those points with different global indices,

*but numbers them with their own **local index**: $i_{loc} = 0, \dots, N_{loc}-1$*

rank 0

rank 1

rank 2

rank 3

u[]

0	1	2	3	4
0	1	2	3	4

0	1	2	3	4
5	6	7	8	9

0	1	2	3	4
10	11	12	13	14

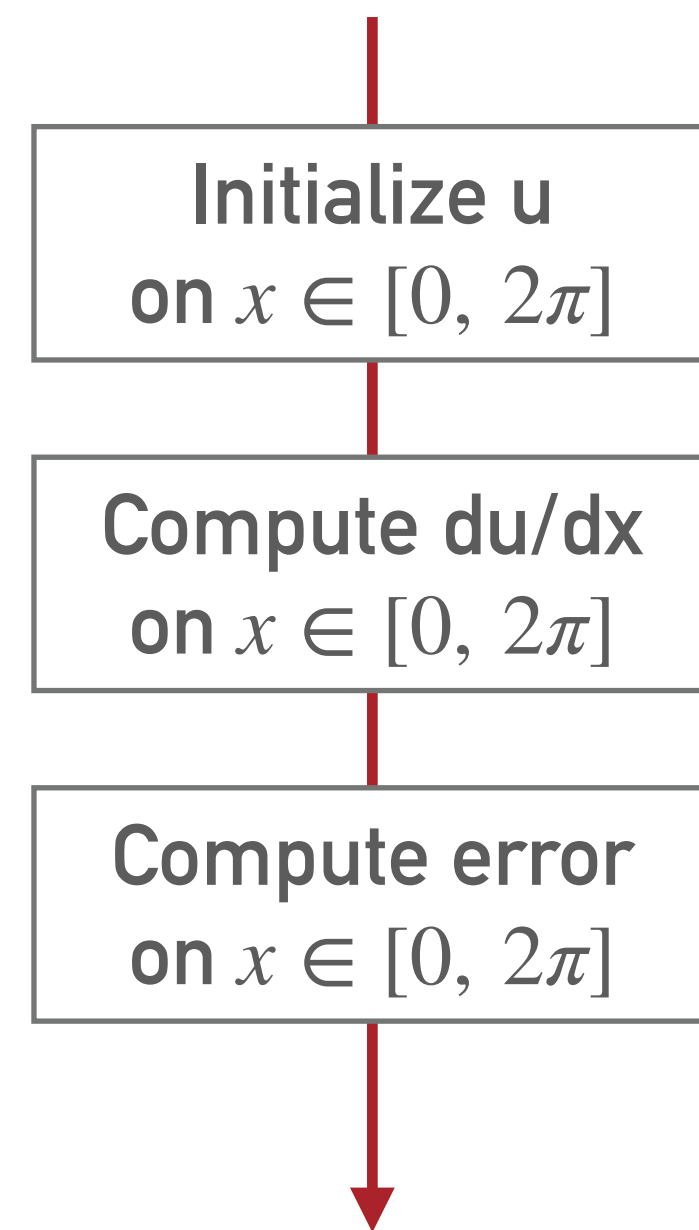

0	1	2	3	4
15	16	17...	18	19

$N_loc = N / nproc$

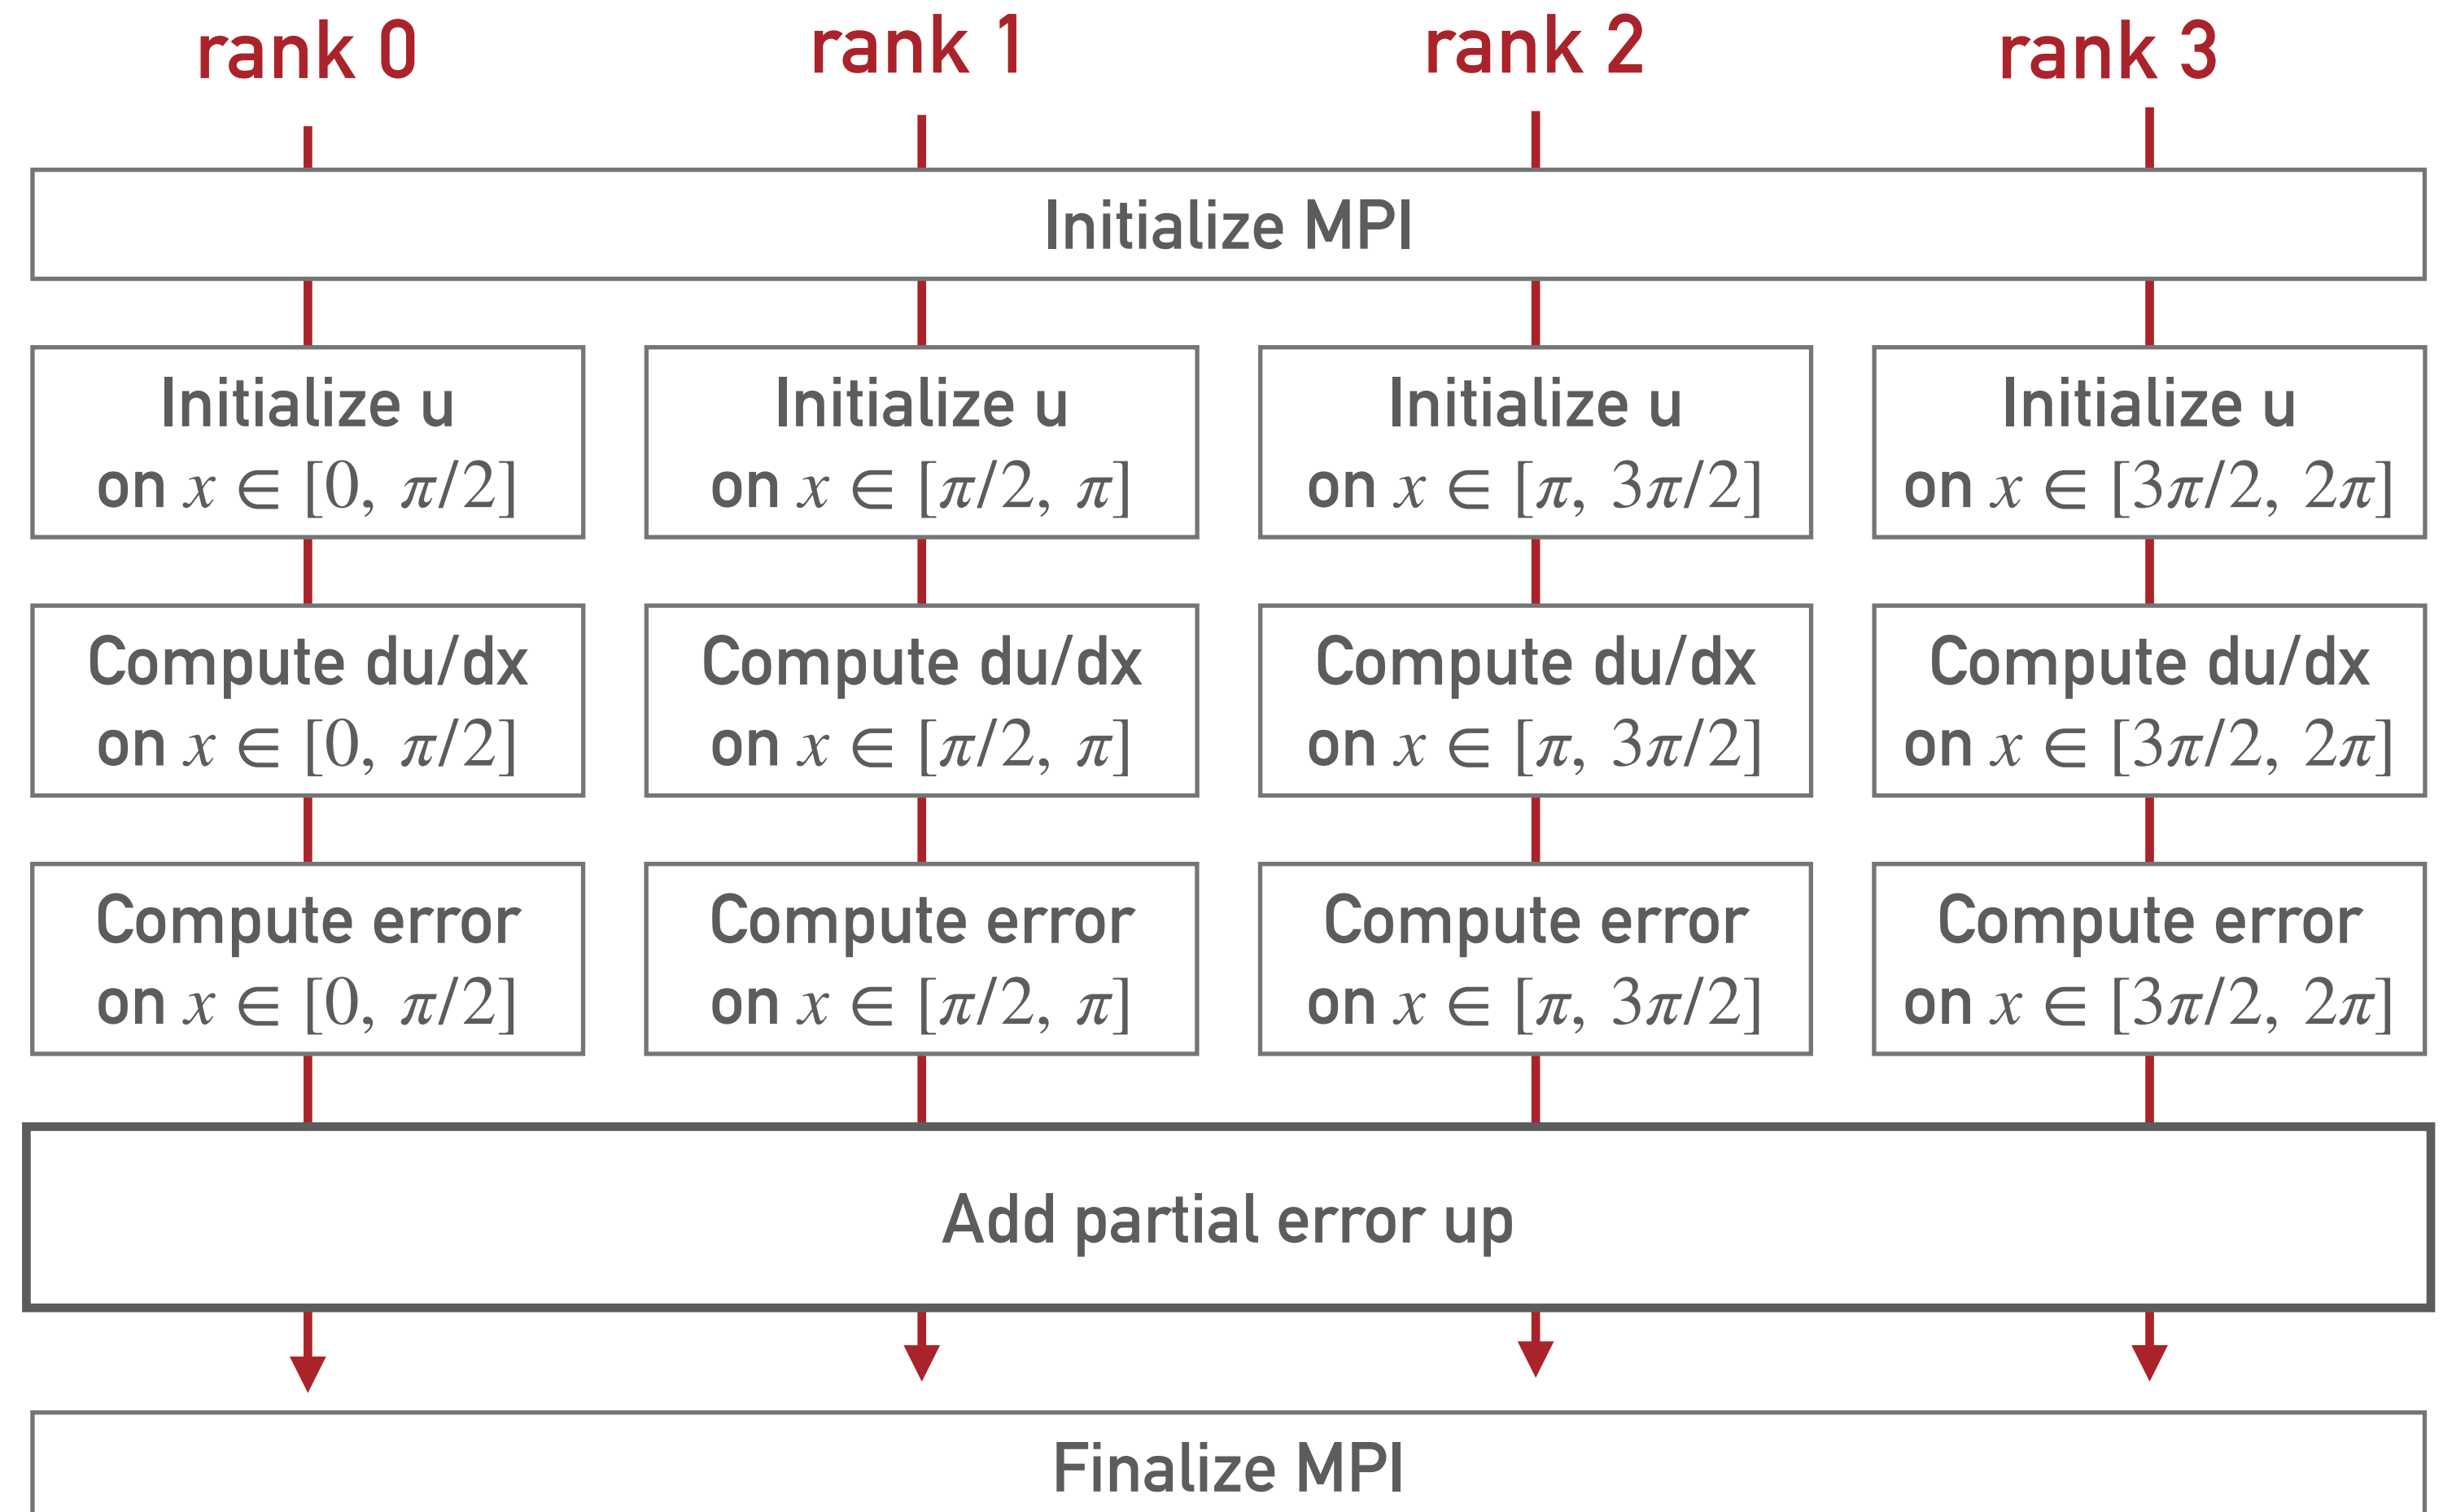

$i = N_loc * irank + i_loc$

DERIVATIVE EXAMPLE

serial program

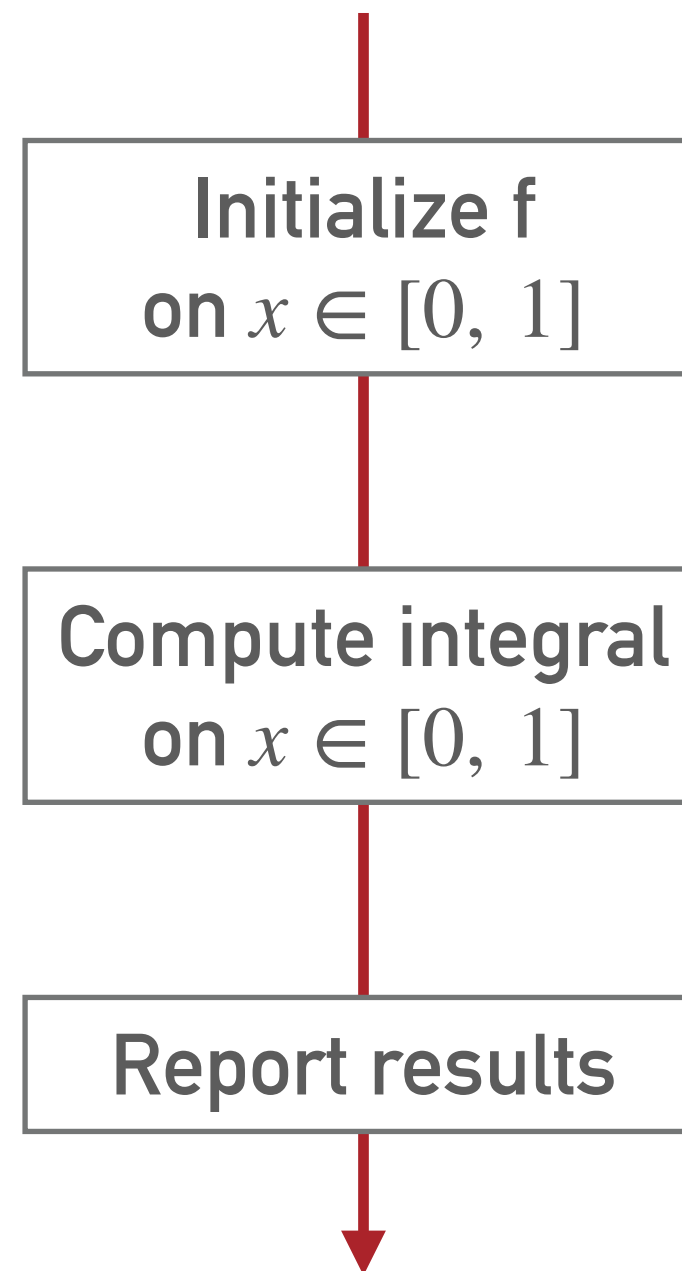

parallel program

EXAMPLE – INTEGRATE A FUNCTION

Integrate $f(x) = \frac{4}{1+x^2}$ on $x \in [0, 1]$ using trapezoidal rule:

$$\int_a^b f(x) dx \approx \sum_{i=0}^{N-1} \frac{1}{2} h (f(x_i) + f(x_{i+1}))$$

We know that exact integral $\int_0^1 \frac{4}{1+x^2} = \pi$

TRAPEZOIDAL RULE EXAMPLE
